Abstract. This paper describes an algebraic approach to the sharing analysis of logic programs based on an abstract domain of set logic programs. Set logic programs are logic programs in which the terms are sets of variables and unification is based on an associative, commutative, and idempotent equality theory. We show that the proposed domain is isomorphic to the set-sharing domain of Jacobs and Langen and argue that there are good reasons to adopt our representation: (1) the abstract domain and the abstract operations defined are based on a theory for sets and set unification, resulting in a more intuitive approach to sharing analysis; (2) the abstract substitutions are like substitutions and can be applied to (abstract) atoms. This facilitates program analyses performed as abstract compilation. Finally (3) our representation makes explicit the “domain” of interest of an abstract substitution – which solves some technical problems in defining the domain of Jacobs and Langen.

1 Introduction

Two variables in a logic program are said to be aliased if in some execution of the program they are bound to terms which contain a common variable. A variable in a logic program is said to be ground if it is bound to a ground term in every execution of the program. Aliasing and groundness information, often called sharing information in the logic programming community, provide the basis for a wide range of program optimizations and other useful applications. Such information can be used to identify circumstances in which the occur check may be safely dispensed with [21, 23] or to determine run-time goal independence which can be used to eliminate costly run-time checks in and-parallel execution of logic programs [20, 16, 14]. In the context of concurrent logic programming languages, sharing information can be used to identify single-writer properties (e.g., structures which are constructed by a single process). One of the more widely applied sharing analyses reported in the literature is the so called set-sharing analysis due to Jacobs and Langen [16], first implemented by Muthukumar and Hermenegildo [20]. This analysis plays a central role in the And-Parallel Prolog compiler described in [14]. The analysis of Jacobs and Langen as well as many of its extensions are developed within the framework of abstract interpretation [8] which provides the basis for a semantic approach to dataflow analysis.
This paper presents an algebraic approach for the sharing analysis of logic programs using set logic programs. In set logic programs terms are sets of variables, and standard unification is replaced by a suitable unification for sets based on the well studied notion of ACI1-unification [1, 17]. Namely, unification in the presence of an associative, commutative, and idempotent equality theory with a unit element (the empty set). Analyses are semantic based and formalized in terms of abstract atoms in which the arguments are sets of variables that specify the possible sharing and definite groundness between the argument positions of concrete atoms. Abstract atoms can also be viewed as abstract substitutions applied to atoms. Abstract substitutions are set substitutions, which are mappings from variables (argument positions) to sets of variables (arguments). We show that the domain of set substitutions is isomorphic to the set-sharing domain. We argue that set logic programs provide a more natural and intuitive means for describing sharing analyses.

The main advantage of our approach is that the operations on the abstract domain and their formal justification follow from simple and obvious algebraic properties of set substitutions. The composition of set substitutions, application of a set substitution to an (abstract) atom, and the projection of a set substitution to a set of relevant variables, all maintain their standard definitions (just as composition, application and projection of usual substitutions). We introduce a natural ordering on abstract syntactic objects which reflects a notion of “less sharing” (similar to “less general” on concrete syntactic objects). The abstract unification of a pair of abstract terms corresponds to finding their most general unifier with respect to this ordering. Unification of abstract atoms is defined as solving sets of unification equations between abstract terms.

Another advantage of the domain we propose is that it enables us to perform program analysis by combining program abstraction (replacing terms by sets of variables) with concrete evaluation (enhanced by ACI1-unification). This approach is often termed abstract compilation and derived from ideas presented in [15, 7, 13] and has been applied in a variety of applications [11, 12, 2, 9]. To our knowledge, no previous work has provided an abstract compilation scheme for sharing information. This is no surprise, since the complexity involved in an accurate analysis for such information makes it a non-trivial task. We attack this problem by formulating abstract compilation as a transformation of logic programs into (abstract) set logic programs. The underlying algebraic framework could be cast in terms of a generalized constraint system, following [13]. This is for example the approach in [22], where (groundness and type) analyses are designed as constraint solving. We prefer to follow a more compact presentation. A similar approach based on ACI-unification has recently been applied to derive polymorphic type dependencies [4].

2 Preliminaries

In the following we assume a familiarity with the standard definitions and notation for logic programs as described in [18]. We assume a first order language
with a fixed set of predicate symbols \( \Pi \), a fixed signature \( \Sigma \) and a countable set of variables \( \mathcal{V} \). The set of atoms constructed using predicate symbols from \( \Pi \) and terms from \( T(\Sigma, \mathcal{V}) \) is denoted by \( B_\mathcal{V} \). The set of variables occurring in a syntactic object \( o \) is denoted \( \text{vars}(o) \).

We assume the standard ordering on terms and other syntactic objects. We let \( t_1 \preceq t_2 \) denote that \( t_1 \) is less general than \( t_2 \). A substitution \( \theta \) is a mapping from \( \mathcal{V} \) to \( T(\Sigma, \mathcal{V}) \) which acts as the identity almost everywhere, i.e., its domain \( \text{dom}(\theta) = \{ x \in \mathcal{V} \mid x \theta \neq x \} \) is finite. The range of a substitution is defined as \( \text{range}(\theta) = \{ x \theta \mid x \in \text{dom}(\theta) \} \). Composition of substitutions \( \theta \) and \( \psi \) is defined as usual and denoted \( \theta \circ \psi \). A substitution \( \psi \) is idempotent if \( \psi \circ \psi = \psi \) (or \( \text{dom}(\psi \circ \psi) = \emptyset \)). The set of idempotent substitutions is denoted \( \text{Sub} \). For substitutions we write \( \theta_1 \preceq \theta_2 \) to denote that \( \theta_1 \) is less general than \( \theta_2 \) if there exists a substitution \( \theta \) such that \( \theta_2 \circ \theta = \theta_1 \). The empty (identity) substitution is denoted \( \varepsilon \). A substitution extends to apply to any syntactic object in the usual way.

We say that a set of variables \( S \) share through a substitution \( \theta \) if there exists a variable \( v \) such that \( S = \{ x \in \text{dom}(\theta) \mid v \in \text{vars}(x \theta) \} \). In this case we say that the variables in \( S \) share in \( \theta \) through \( v \). Jacobs and Langen denote this as 

\[
\text{occs}(\theta, v) = S \ [16].
\]

Similarly, for an atom \( p(t_1, \ldots, t_n) \) we say that the set of argument positions \( I \subseteq \{1, \ldots, n\} \) share if there exists a variable \( v \) such that \( I = \{ i \mid v \in \text{vars}(t_i) \} \). In this case we might say that the argument positions \( I \) in \( p(t_1, \ldots, t_n) \) share through \( v \).

### 3 Set Logic Programs

The sharing analyses described in this paper are constructed using a first order language, similar to that of logic programs, which we call set logic programs. Intuitively, set logic programs are logic programs in which the terms are sets of variables, which we call abstract terms.

**Abstract terms:** Syntactically, we assume a set of variables \( \mathcal{V} \) and an underlying alphabet \( \Sigma^\oplus = \{ \oplus, \emptyset \} \) consisting of a binary function symbol \( \oplus \) which “glues” elements together and a single constant symbol \( \emptyset \) to represent the empty set. Abstract terms, or set expressions, are elements of the term algebra \( T(\Sigma^\oplus, \mathcal{V}) \) modulo an equality theory consisting of the following axioms:

\[
\begin{align*}
(x \oplus y) \oplus z &= x \oplus (y \oplus z) \quad \text{(associativity)} \\
x \oplus x &= x \quad \text{(idempotence)} \\
x \oplus y &= y \oplus x \quad \text{(commutativity)} \\
x \oplus \emptyset &= x \quad \text{(unit element)}
\end{align*}
\]

This equality theory is sometimes referred to as \( AC1 \) and the corresponding equivalence relation on terms denoted \( =_{AC1} \). This notion of equivalence suggests that abstract terms can be viewed as sets of variables. For example, the terms \( x_1 \oplus x_2 \oplus x_3, x_1 \oplus x_2 \oplus x_3 \oplus \emptyset, \text{ and } x_1 \oplus x_2 \oplus x_3 \oplus x_2 \) can each be viewed as representing the set \( \{ x_1, x_2, x_3 \} \) of three variables. In the following we do not distinguish between set expressions and sets of variables, often referring to the set of variables in a term as a set expression.
Abstract atoms: Abstract atoms are entities of the form \( p(\tau_1, \ldots, \tau_n) \) where \( p/n \in \Pi \) and \( \tau_1, \ldots, \tau_n \) are abstract terms. Abstract atoms are also viewed modulo ACII-equivalence. Namely, two abstract atoms are equivalent, denoted \( \pi_1 =_{ACII} \pi_2 \), if their corresponding arguments are equivalent. We denote the set of abstract atoms modulo ACII-equivalence by \( B^o_\Pi \). In order to simplify notation we often write an abstract atom \( \pi \) instead of its corresponding equivalence class \( [\pi] =_{ACII} \). We also denote ACII-equality ("\( =_{ACII} \)") of abstract atoms by equality sign ("\( = \)" when it is unambiguous.

While our abstract domain is defined in terms of abstract atoms, abstract substitutions also play a role in the presentation. Moreover, abstract substitutions are used later to show the isomorphism between our domain and the set-sharing domain of Jacobs and Langen.

Abstract substitutions: Abstract substitutions, or set substitutions, are substitutions which map variables of \( \mathcal{V} \) to abstract terms. We denote the set of idempotent abstract substitutions by \( \text{Sub}^0 \). The application of an abstract substitution \( \mu \) to an abstract term \( \tau \) is defined as usual by replacing occurrences of each variable \( x \) in \( \tau \) by the abstract term \( \mu(x) \). We say that two abstract substitutions \( \mu_1 \) and \( \mu_2 \) are ACII-equivalent if they map variables to equivalent abstract terms,

\[
\mu_1 =_{ACII} \mu_2 \iff \forall x \in \mathcal{V} : x\mu_1 =_{ACII} x\mu_2.
\]

The standard operations on abstract substitutions such as projection and composition are defined just as for usual substitutions.

We say that an abstract substitution \( \psi \) is linear if

\[
\forall x, y \in \text{dom}(\psi) : x \neq y \Rightarrow x\psi \cap y\psi = \emptyset.
\] (1)

Our interest in linear substitutions is due to the fact that they do not introduce additional sharing dependencies when applied to a syntactic object. Namely, if \( x \) and \( y \) are distinct variables and \( \psi \) is a linear abstract substitution then \( x\psi \) and \( y\psi \) do not have any variables in common. Linear substitutions induce an ordering on syntactic objects which reflects the “amount” of sharing they contain.

An ordering: We say that an abstract atom \( \pi_1 \) is less general than \( \pi_2 \), denoted \( \pi_1 \preceq \pi_2 \), if and only if there is a linear substitution \( \psi \) such that \( \pi_1 =_{ACII} \pi_2\psi \). It is straightforward to show that \( \pi_1 \preceq \pi_2 \) implies that the arguments of \( \pi_2 \) contain more sharing and less groundness than the arguments of \( \pi_1 \). Namely, if \( I \) is a set of argument positions which share in \( \pi_1 \) (through some variable), then \( I \) also share in \( \pi_2 \) (through some variable). Moreover, if \( \pi_2 \) binds a variable \( x \) to the empty set, then so must \( \pi_1 \).

Example 1. Consider the following abstract atoms:

\[
\pi_1 = p(\{A, B\}, \{B, C\}, \{A, B, D\}), \quad \pi_2 = p(\{X\}, \{X, Y\}, \{X, Z\}),
\]

\[
\pi_3 = p(\{U\}, \{V\}, \{U, W\}).
\]
The first and the third arguments of \( \pi_1 \) share through \( A \), while all three arguments share through \( B \). In \( \pi_2 \) there is sharing between all three arguments through \( X \), and in \( \pi_3 \) there is sharing between the first and the third argument. Thus, \( \pi_1 \) contains more sharing than each of \( \pi_2 \) and \( \pi_3 \). In our domain this is captured as \( \pi_2 \preceq \pi_1 \) and \( \pi_3 \preceq \pi_1 \).

This because \( \pi_2 = \pi_1 \psi_1 \) and \( \pi_3 = \pi_1 \psi_2 \) where:

\[
\psi_1 = \{ A \mapsto \emptyset, \ B \mapsto X, \ C \mapsto Y, \ D \mapsto Z \}
\]

\[
\psi_2 = \{ A \mapsto U, \ B \mapsto \emptyset, \ C \mapsto V, \ D \mapsto W \}.
\]

Note also that the ordering “\( \preceq \)” naturally induces the ACII-equivalence of atoms, i.e., \( (\pi_1 \preceq \pi_2) \land (\pi_2 \preceq \pi_1) \iff (\pi_1 =_{ACII} \pi_2) \).

A similar ordering is defined for abstract substitutions. An abstract substitution \( \mu_1 \) is less general than \( \mu_2 \), denoted \( \mu_1 \preceq \mu_2 \), if and only if there exists a linear substitution \( \psi \) such that \( \mu_2 \circ \psi =_{act} \mu_1 \). Note that if \( \mu_1 \preceq \mu_2 \) and \( \mu_2 \preceq \mu_1 \) then \( \mu_1 \) and \( \mu_2 \) map variables to ACII-equivalent terms and are hence ACII-equivalent.

**Least upper bound:** The least upper bound of two abstract atoms with the same predicate symbol and arity is induced by the ordering of abstract objects.

**Proposition 1.** For two abstract atoms \( p(\tau_1, \ldots, \tau_n) \) and \( p(\tau'_1, \ldots, \tau'_n) \) of the same predicate symbol \( p/n \):

\[
p(\tau_1, \ldots, \tau_n) \uplus p(\tau'_1, \ldots, \tau'_n) = p(\tau_1 \oplus \tau'_1, \ldots, \tau_n \oplus \tau'_n).
\]

**Proof.** Technical.

The notion of least upper bound extends to sets of abstract atoms by combining all of the atoms with the same predicate symbol. Let \( I \subseteq B') \), then

\[
\uplus I = \{ \uplus \{ p(\tau_1, \ldots, \tau_n) \in I \} \mid p/n \in \Pi \}.
\] (2)

### 4 An Abstract Domain for Sharing Analysis

We propose set logic programs as a formal basis for studying sharing properties of logic programs. The sets of variables in the arguments of an abstract atom represent possible sharing information in corresponding concrete arguments. The formal relation between concrete atoms and abstract atoms is given in terms of an abstraction function on atoms which replaces the concrete terms in an atom by the set of variables it contains.

\[
\sigma : T(\Sigma, V) \rightarrow T(\Sigma^\oplus, V)
\]

\[
\sigma(t) = \begin{cases} 
\emptyset & \text{if } \text{vars}(t) = \emptyset \\
\{ x_1 \oplus \cdots \oplus x_n \} & \text{if } \text{vars}(t) = \{ x_1, \ldots, x_n \}, \ n > 0 
\end{cases}
\]

(3)

The abstraction of atoms is obtained by application of term abstraction separately to each argument:

\[
\sigma : B \rightarrow B^\oplus
\]

\[
\sigma(p(t_1, \ldots, t_n)) = p(\sigma(t_1), \ldots, \sigma(t_n))
\]

(4)
Example 2. Consider the concrete atom \( a = p([X, Y | X s], f(Y s), g(X, Y, Z)) \). Its abstraction is:

\[
\sigma(a) = \sigma(p([X, Y | X s], f(Y s), g(X, Y, Z)) = p(X Y s, X Y Z)
\]

where the equivalence of the last two atoms is provided by the pair of linear substitutions: \( \psi_l = \{ Y \mapsto \emptyset, X \mapsto X' \} \) and \( \psi_g = \{ X' \mapsto (X Y) \} \).

We say that an abstract atom \( \pi \) describes a concrete atom \( a \) if \( \sigma(a) \preceq \pi \), denoted \( \pi \preceq a \). Namely, if the arguments of \( \pi \) contain more sharing than those of \( a \), and if any argument position of \( \pi \) which is ground is also ground in \( a \).

Abstraction of substitutions: Abstract atoms and abstract substitutions are in fact two equivalent representations of the same dependency information. Moreover, abstract atoms are no more than “syntactic sugar” for \( \Pi \times \text{Sub}^0 \). However, abstract substitutions are sometimes more convenient objects to reason about. Thus, similarly to the case of atoms, we define the notions of abstraction and approximation for substitutions. A substitution is abstracted by abstracting the terms in its range:

\[
\sigma: \text{Sub} \rightarrow \text{Sub}^0
\]

\[
\sigma(\theta) = \{ x \mapsto \sigma(t) \mid [x \mapsto t] \in \theta \}.
\] (5)

We say that an abstract substitution \( \mu \) describes a concrete substitution \( \theta \), denoted \( \mu \preceq \theta \), if \( \sigma(\theta) \preceq \mu \).

Abstract interpretations: An abstract domain for sharing analysis and the corresponding abstraction and concretization functions are obtained by considering abstract interpretations, i.e., sets of abstract atoms. We view sets of abstract atoms as being downwards-closed. A set \( S \in \varphi(\mathcal{B}_V^0) \) is downwards-closed if \( \pi \in S \) and \( \pi' \preceq \pi \) implies \( \pi' \in S \). We equip \( \mathcal{B}_V^0 \) with an ordering defined as

\[
I_1 \preceq I_2 \iff \forall \pi_1 \in \sqcup I_1 \exists \pi_2 \in \sqcup I_2 : \pi_1 \preceq \pi_2.
\] (6)

The corresponding equivalence relation:

\[
I_1 \approx I_2 \iff (I_1 \preceq I_2) \land (I_2 \preceq I_1)
\] (7)

provides a basis for relating abstract interpretations to downwards-closed sets of (abstract) atoms (also called c-interpretations in [10]). Let \( \mathcal{S}_I \) denote a minimal downwards-closed set containing \( S \). Equation (7) provides \( S \approx \mathcal{S}_I \) for any \( S \in \varphi(\mathcal{B}_V^0) \), i.e., any member of \( \varphi(\mathcal{B}_V^0) \) is equivalent to some downwards-closed set. The quotient \( \varphi(\mathcal{B}_V^0) \approx \) of the equivalence relation will be denoted in the following by an abuse of notation as \( \varphi(\mathcal{B}_V^0) \).

**Lemma 2.** \((\varphi(\mathcal{B}_V^0), \preceq)\) is a complete lattice.

**Proof.** If \( L \) is a set of downwards-closed sets then \( \cap L \) and \( \sqcup L \) are downwards-closed, therefore \( \text{lub}(L) \approx \sqcup L \) and \( \text{glb}(L) \approx \cap L \).
The relation between concrete and abstract interpretations is formalized as usual in terms of a pair of abstraction and concretization functions lifted from the abstraction function $\sigma$ on atoms in the standard way:

$$\alpha : \varphi(B_Y) \rightarrow \varphi(B_Y^{\circ}) \quad \gamma : \varphi(B_Y^{\circ}) \rightarrow \varphi(B_Y)$$

$$\alpha(I) = \bigcup \{ \alpha(a) \mid a \in I \} \quad \gamma(I) = \bigcup \{ I \mid \alpha(I) \subseteq I \}$$

(8)

**Theorem 3.** $(\varphi(B_Y), \alpha, \varphi(B_Y^{\circ}), \gamma)$ is a Galois insertion.

**Proof.** Straightforward from the above definitions.

In order to ensure terminating analysis and finite approximations we establish finiteness of our abstract domain modulo the equivalence relation of Equation (7). But first note that for any abstract interpretation $I$, $I \approx \sqcup I$. This follows by Equation (6). Intuitively, this means that we view abstract interpretations as “hubbled”. It is worth noting that $\sqcup I$ is an abstract interpretation with minimal cardinality among those equivalent to $I$, containing at most one abstract atom for each predicate symbol in $\Pi$.

**Theorem 4.** $B_Y^{\circ}$ is finite.

**Proof.** The elements of $B_Y^{\circ}$ are equivalence classes of abstract atoms $[\pi]_{\approx =}$.

Therefore it suffices to prove that for any predicate symbol $p/n$ the number of associated equivalence classes of abstract atoms $[\pi]_{= \approx}$ is finite. We prove the claim of the theorem demonstrating that each equivalence class of abstract atoms constructed using $p/n$ has a representative with a number of variables bounded by $2^n - 1$. Assume an atom $\pi$ has more than $2^n - 1$ distinct variables. Then there are at least two variables $x$ and $y$ occurring in exactly the same set of argument positions of $\pi$. Consider the atom $\pi' = \pi \cdot \{x \mapsto \emptyset, y \mapsto z\}$ where $z$ is a fresh variable. By construction we have $\pi' \preceq \pi$ and it is easy to see that $\pi \npreceq \pi'$ with $\pi = \pi' \cdot \{z \mapsto (x \oplus y)\}$. Thus, $\pi$ and $\pi'$ are in the same equivalence class and $|\text{vars}(\pi')| = |\text{vars}(\pi)| - 1$. It follows that for any atom having two or more variables in the same set of argument positions we can find an equivalent atom with a smaller set of variables. So, for any atom constructed using $p/n$ there exists an equivalent atom with all variables occurring in distinct subsets of argument positions, i.e., an atom with at most $2^n - 1$ variables.

The abstract domain $(\varphi(B_Y), \alpha, \varphi(B_Y^{\circ}), \gamma)$ provides a basis for the sharing analysis of logic programs. When constructing a program analysis for logic programs three main operations must be defined: abstract unification, abstract application (or projection$^3$), and abstract least upper bound. We show that all of these operations are straightforward to define in our domain.

---

$^3$ The role of projection is to restrict a substitution to a set of variables of interest. Using application instead facilitates the design of the analysis.
**Abstract Unification:** Formally speaking, the unification of abstract atoms is similar to the well studied notion of AC11-unification \[1, 17\]. Recall that an AC11-unifier of two terms \( \tau_1, \tau_2 \) is a substitution \( \psi \) such that \( \tau_1 \psi = AC11 \tau_2 \psi \). However, there are two important differences: (1) because the underlying alphabet contains only one binary function symbol and only one constant, abstract terms always unify\(^4\) and have exactly one most general unifier (in the general case there may be a finite number of most general unifiers and the unification problem is NP-complete). And (2) because we define the ordering on terms using the notion of linear substitutions, the most general unifier is non-standard (though well defined).

The abstract unification (for sharing analysis) of a pair of terms \( \tau_1, \tau_2 \), denoted \( mgu_{AC11}(\tau_1, \tau_2) \), is the most general substitution \( \mu \) such that \( \tau_1 \mu = AC11 \tau_2 \mu \). Figure 1 describes a simple algorithm to compute the most general unifier of a pair of abstract terms. Note in the figure that if \( \tau_1 \) or \( \tau_2 \) is ground then \( S = \emptyset \) and \( Z = \emptyset \) which implies that \( \mu \) binds all variables to \( \emptyset \).

**Lemma 5.** Let \( t_1 \) and \( t_2 \) be concrete terms with \( \theta = mgu(t_1,t_2) \). Let \( \xi = mgu_{AC11}(\sigma(t_1),\sigma(t_2)) \), computed by the algorithm in Figure 1. Then \( \xi \sim \theta \).

**Proof.** Technical, by observing that the algorithm in Figure 1 enables all possible sharing which might occur in the unification of \( t_1 \) and \( t_2 \). If \( \theta \) implies less sharing than that, a linear abstract substitution \( \psi \) can be constructed such that it maps out the extra sharing, and therefore \( \xi \circ \psi = \sigma(\theta) \).

The abstract unification \( mgu^A(\pi_1, \pi_2) \) of atoms \( \pi_1 \) and \( \pi_2 \) is defined in terms of the set \( \mathcal{E} \) of equations between the terms in the corresponding argument positions by:

\[
mgu^A(\mathcal{E}) = \begin{cases} 
\emptyset & \text{if } \mathcal{E} = \emptyset \\
\mu \circ mgu^A(\mathcal{E}' \mu) & \text{if } \mathcal{E} = \{(\tau = \tau')\} \cup \mathcal{E}' \\
& \text{and } \mu = mgu_{AC11}(\tau_1, \tau_2)
\end{cases}
\]

Abstract unification is thus defined much the same as in the concrete case. It is parameterized on abstract unification of terms and abstract composition of substitutions. The following result about abstract composition is instrumental in proving correctness of abstract unification.

**Lemma 6.** Let \( \theta_1 \) and \( \theta_2 \) be concrete substitutions, and \( \mu_1 \) and \( \mu_2 \) abstract substitutions such that \( \mu_1 \sim \theta_1 \) and \( \mu_2 \sim \theta_2 \). Then \( (\mu_1 \circ \mu_2) \sim (\theta_1 \circ \theta_2) \).

**Proof.** Since \( \mu_1 \sim \theta_1 \) and \( \mu_2 \sim \theta_2 \), we have that \( \exists \psi_1 : \mu_1 \circ \psi_1 = \sigma(\theta_1) \) and \( \exists \psi_2 : \mu_2 \circ \psi_2 = \sigma(\theta_2) \). We have to prove that \( \exists \psi : \mu_1 \circ \mu_2 \circ \psi = \sigma(\theta_1 \circ \theta_2) \). It is easy to see that this holds with \( \psi = \psi_1 \circ \psi_2 \).

\(^4\) Observe that the substitution which binds all variables in two terms to \( \emptyset \) is always a unifier.
Input: abstract terms $\tau_1$ and $\tau_2$
Output: most general AC1-unifier $\mu$

\[
\begin{align*}
  v_1 &= \text{vars}(\tau_1) \\
  v_2 &= \text{vars}(\tau_2) \\
  S &= \{ s \subseteq (v_1 \cup v_2) \mid s \cap v_1 \neq \emptyset, s \cap v_2 \neq \emptyset \} \\
  \text{let } S &= \{s_1, \ldots, s_k\} \\
  Z &= \{z_1, \ldots, z_h\} \quad /\text{ fresh variables corresponding to members of } S \\
  \mu &= \left\{ x \mapsto z_1 \oplus \cdots \oplus z_n \mid x \in (v_1 \cup v_2), \{z_1, \ldots, z_n\} = \{z_i \mid \exists s_i \in S\} \right\}
\end{align*}
\]

Fig. 1. AC1-unification of two terms

**Theorem 7 abstract unification is correct.**
Let $a_1$ and $a_2$ be concrete atoms such that $\text{mgu}(a_1, a_2) = \theta$. Let $\pi_1$ and $\pi_2$ be abstract atoms such that $\pi_1 \propto a_1$ and $\pi_2 \propto a_2$. Let $\mu = \text{mgu}^A(\pi_1, \pi_2)$. Then $\mu \propto \theta$.

**Proof.** By induction on the length of corresponding tuples of abstract terms with base case provided by Lemma 5 and the induction step provided by Lemma 6.

The result of Theorem 7 is one of the main points in our presentation. It shows that there is a natural ordering (based on linear substitutions) for set-sharing analysis for which abstract unification is defined as inductive solving equations similarly to the case of concrete unification.

**Abstract application**: The application of an abstract substitution to an abstract atom is defined just as for the case of a standard substitution. The correctness for sharing analysis follows as a corollary from Theorem 7.

**Corollary 8 application of abstract mgu is correct.**
Let $a_1$ and $a_2$ be concrete atoms, and $\pi_1$ and $\pi_2$ be abstract atoms. Let $\pi_1 \propto a_1$ and $\pi_2 \propto a_2$, with $\text{mgu}(a_1, a_2) = \theta$ and $\text{mgu}^A(\pi_1, \pi_2) = \mu$. Let $h$ be a concrete atom. Then $\sigma(h)\mu \propto h\theta$.

**Proof.** From Theorem 7 it holds $\sigma(a_1\theta) \preceq \pi_1\mu$, which implies that $\sigma(h, a_1)\theta \preceq (\sigma(h), \pi_1)\mu$. Thus, $\sigma(h\theta) \preceq (\sigma(h))\mu$.

**Abstract lub**: It is easy to see that the least upper bound operation on abstract atoms of Section 3 is safe, and precise, for sharing analysis.

**Lemma 9 abstract lub is correct.**
For abstract atoms $\pi_1$ and $\pi_2$ and concrete atoms $a_1$ and $a_2$,

\[
(\pi_1 \propto a_1) \land (\pi_2 \propto a_2) \Rightarrow (\pi_1 \sqcup \pi_2 \propto a_1) \land (\pi_1 \sqcup \pi_2 \propto a_2).
\]
Proof. Straightforward. Since $\pi_1 \uplus \pi_2$ is an upper bound of $\pi_1$ and $\pi_2$ we have $\pi_1 \preceq (\pi_1 \uplus \pi_2)$ and $\pi_2 \preceq (\pi_1 \uplus \pi_2)$. Because $\pi_1 \prec a_1$ and $\pi_2 \prec a_2$ we have $\sigma(a_1) \preceq \pi_1$ and $\sigma(a_2) \preceq \pi_2$. Thus, $\sigma(a_1) \preceq (\pi_1 \uplus \pi_2)$ and $\sigma(a_2) \preceq (\pi_1 \uplus \pi_2)$, i.e., $\pi_1 \uplus \pi_2 \prec a_1$ and $\pi_1 \uplus \pi_2 \prec a_2$.

When considering the lub of abstract interpretations, the operation is trivially precise as the ordering of Equation (7) already views interpretations as “lubbed”. It follows that $\gamma$ is indeed well defined, as $I \approx \mathcal{I}$ and $\gamma(I) = \gamma(\mathcal{I})$.

5 Set Logic Programs vs Set-Sharing

We show that the abstract domain based on set logic programs is isomorphic to the well-known set-sharing representation of Jacobs and Langen [16]. In the following we denote by Sharing the abstract domain of [16].

We say that two abstract domains of a given concrete domain are isomorphic if (1) they are isomorphic as partial orders; and (2) the interpretation of the corresponding abstract objects is the same. Namely, the closure operators $\gamma \circ \alpha$ defined by the corresponding abstraction and concretization functions are the same.

The domain of set-sharing: Recall the original definition of the Sharing domain which consists of sets of sets of program variables ordered by set inclusion. Sharing information is characterized using a notion of the occurrences of a variable through a substitution,

$$\text{occs} : (\text{Sub} \times \mathcal{V}) \rightarrow \wp(\mathcal{V})$$

$$\text{occs}(\theta, v) = \{ x \in \text{dom}(\theta) \mid v \in \text{vars}(x\theta) \}. $$

If $\text{occs}(\theta, v) = S$ then $S$ is the set of variables which $\theta$ maps to a term containing $v$. Each set $S$ in an abstract substitution $\kappa$ represents the possibility of a variable $v$ occurring through the variables of $S$ in the range of a substitution described by $\kappa$. The abstraction function for the sharing domain is defined in terms of the sharing groups of a substitution, formalized by:

$$A : \text{Sub} \rightarrow \text{Sharing}$$

$$A(\theta) = \{ \text{occs}(\theta, v) \mid v \in \text{vars}(\text{range}(\theta)) \}. $$

A Galois insertion is then constructed:

$$\alpha^{Sh} : \wp(\text{Sub}) \rightarrow \text{Sharing}$$

$$\alpha^{Sh}(\theta) = \bigcup \{ A(\theta) \mid \theta \in \Theta \}$$

$$\gamma^{Sh} : \text{Sharing} \rightarrow \wp(\text{Sub})$$

$$\gamma^{Sh}(\kappa) = \{ \theta \in \text{Sub} \mid A(\theta) \subseteq \kappa \} $$

The following example illustrates the description of concrete substitutions by set-sharing substitutions.

Example 3. Let $\kappa = \{ \{A, B\}, \{B, C\}, \{A\}, \{B\}, \{C\}, \emptyset \}$ be an abstract substitution in the Sharing domain. The substitutions $\theta_1 = \{A \mapsto f(X, Y), B \mapsto g(Y, Z), C \mapsto f(Z, V)\}$ and $\theta_2 = \{A \mapsto f(X), B \mapsto g(Y), C \mapsto f(Z)\}$ are described by $\kappa$: In $\theta_1$, $X$ occurs through $\{A\}$, $Y$ occurs through $\{A, B\}$, $Z$ occurs through $\{B, C\}$ and $V$ occurs through $\{C\}$, and in $\theta_2$ there are variables which occur through $\{A\}$, $\{B\}$ and $\{C\}$ — and these occurrences are all specified in $\kappa$. 
An isomorphism: In principle the domain based on set logic programs is formalized in terms of a Galois insertion of abstract atoms while the set-sharing domain of Jacobs and Langen is based on a Galois insertion of abstract substitutions. This introduces some technicalities into the formal proofs. The reader should notice that in fact set-sharing analyses, such as those used in [16, 20], are actually based on pairs consisting of a concrete atom of the form $p(x_1, \ldots, x_n)$ together with an abstract substitution.\(^5\) Note that an abstract atom $p(\tau_1, \ldots, \tau_n)$ in our domain can also be viewed as a pair $p(x_1, \ldots, x_n)$ together with a substitution $\{x_1 \mapsto \tau_1, \ldots, x_n \mapsto \tau_n\}$.

**Lemma 10.** There exists a set isomorphism between $\text{Sub}^\circ$ and $\text{Sharing}$. 

**Proof.** Note that the abstraction function $A: \text{Sub} \to \text{Sharing}$ extends naturally to a function $A: \text{Sub}^\circ \to \text{Sharing}$ viewing sets of variables as ordinary terms. Hence, we prove the lemma demonstrating that $A: \text{Sub}^\circ \to \text{Sharing}$ is a bijective function for which an inverse function $A^{-1}: \text{Sharing} \to \text{Sub}^\circ$ can be provided.

Let $\kappa = \{S_1, \ldots, S_n\}$ be an element of the $\text{Sharing}$ domain defined for a set $D$ of variables of interest. Assume without loss of generality that the domain of substitutions in $\text{Sub}^\circ$ is $D$.\(^6\) Let $z_1, \ldots, z_n$ be a set of fresh variables, one for each sharing group in $\kappa$. The inverse function yielding the set substitution $\mu$ which corresponds to $\kappa$ is defined by:

$$A^{-1}: \text{Sharing} \to \text{Sub}^\circ$$

$$A^{-1}(\kappa) = \left\{ x \mapsto \bigoplus_{x \in S_i} z_i \mid x \in D \right\}.$$ 

It is straightforward to see that $A \circ A^{-1}$ and $A^{-1} \circ A$ correspond to identity functions in $\text{Sub}^\circ$ and $\text{Sharing}$ respectively.

The following lemma establishes the relation between the ordering of set substitutions and the ordering in the $\text{Sharing}$ domain:

**Lemma 11.** There is an order embedding between $\langle \text{Sub}^\circ, \preceq \rangle$ and $\langle \text{Sharing}, \subseteq \rangle$.

**Proof.** Let $\mu_1$ and $\mu_2$ be two abstract substitutions and let $D$ be a set of variables of interest. Assume without loss of generality that $\text{dom}(\mu_1) = \text{dom}(\mu_2) = D$. We prove that $\mu_1 \preceq \mu_2 \iff A(\mu_1) \subseteq A(\mu_2)$.

$(\Rightarrow)$ We have to demonstrate that if $\mu$ is a set substitution and $\psi$ is a linear substitution then $A(\mu \psi) \subseteq A(\mu)$. Each member of the set $A(\mu \psi)$ is of the form: $\text{occs}(\mu \psi, v) = \{ x \mid v \in \text{vars}(x \mu \psi) \}$ . Assume without loss of generality that $\text{range}(\mu) = \text{dom}(\psi)$. Since $\psi$ is linear, there is exactly one variable $v' \in \text{range}(\mu)$.

\(^5\) However, set-sharing substitutions cannot be applied to atoms, since they are in fact an encoding of sharing information rather than “true” substitutions. 

\(^6\) Note that the domain of an abstract substitution $\kappa \in \text{Sharing}$ must be explicitly specified, as any variable of interest not occurring in $\kappa$ is considered ground. In contrast, the variables of interest for a set substitution are those in its domain.
mapped by \( \psi \) to a set expression containing \( v \). Thus, all the variables occurring in \( \mu \psi \) through \( v \) occur in \( \mu \) through \( \psi' \), i.e., \( ocecs(\mu \psi, v) = ocecs(\mu, \psi') \). And so, we have \( ocecs(\mu \psi, v) \in A(\mu) \).

\( \iff \) Given \( A(\mu_1) \subseteq A(\mu_2) \) we construct a linear substitution \( \psi \) as follows. Consider the set of variables: \( S = \{ v | ocecs(\mu_2, v) \in A(\mu_2) \setminus A(\mu_1) \} \). For any variable \( v \in S \) we add a mapping \( \{ v \rightarrow \emptyset \} \) to \( \psi \). Thus, we have \( A(\mu_2 \psi) = A(\mu_1) \) and consequently, by Lemma 10, \( \mu_1 \psi = \mu_2 \).

Thus, set substitutions of \( \text{Sub}^\oplus \) and abstract substitutions of \( \text{Sharing} \) form isomorphic partial orders. Considering abstract substitutions together with predicate names we establish that both abstract domains approximate the same sharing information.

**Theorem 12** domain isomorphism.

\( (\Pi \times \text{Sharing}, \subseteq, \alpha^{sh}) \cong (\wp(\mathcal{B}^\oplus_\psi), \subseteq, \alpha) \)

**Proof.** Technical, by Lemmas 10 and 11 and by observing that \( A : \text{Sub} \rightarrow \text{Sharing} \) and \( \sigma : \text{Sub} \rightarrow \text{Sub}^\oplus \) map concrete substitutions to isomorphic abstract substitutions. Namely, that \( \forall \theta \in \text{Sub} : A(\theta) = A(\sigma(\theta)) \), which follows by definition.

The following example illustrates the isomorphism of the two representations of sharing information.

**Example 4.** Recall the abstract substitution \( \kappa \) and the concrete substitutions \( \theta_1 \) and \( \theta_2 \) of Example 3. Consider the set substitution, \( \mu = \{ A \mapsto \{ X, U \}, B \mapsto \{ X, Y, V \}, C \mapsto \{ Y, W \} \} \). The substitutions \( \theta_1 \) and \( \theta_2 \) are described by \( \mu \): \( X \) indicates the possible sharing of \( A \) and \( B \), \( Y \) indicates that of \( B \) and \( C \), and \( U \), \( V \) and \( W \) the possible presence in \( A \), \( B \) and \( C \) of variables not shared with other variables. The abstract substitution \( \kappa \) and the set substitution \( \mu \) also describe the substitutions \( \theta_3 = \{ A \mapsto f(X), B \mapsto g(X) \} \) and \( \theta_4 = \{ A \mapsto f(X, Y), B \mapsto g(X, Y), C \mapsto Z \} \).

**6 Sharing Analysis with Set Logic Programs**

The abstract operations defined in Section 4 (unification, application, least upper bound) provide the building blocks to construct an abstract semantics for the sharing analysis of logic programs. We have constructed several such program analyses. A bottom-up approach is described in [5]. A top-down approach based on tabulation using XSB is described in [3]. In this section we illustrate as an example a bottom-up approach based on an abstract immediate consequences operator \( \mathcal{T}_P : \wp(\mathcal{B}^\oplus_\psi) \rightarrow \wp(\mathcal{B}^\oplus_\psi) \) for set logic programs. For a logic program \( P \) the least fixed point of \( \mathcal{T}_{\sigma(P)} \) provides the sharing analysis for \( P \).

\[
\mathcal{T}_P(I) = \cup \left\{ \left. \{ h (b_1, \ldots, b_n \in P, \ a_1, \ldots, a_n \in I | \mu = mgua((b_1, \ldots, b_n), (a_1, \ldots, a_n)) \right\} \right\}. \tag{11}
\]

Let us consider the analysis of the well-known \textit{append} program depicted in Figure 2 (left) using the technique discussed above. The analysis is obtained
as a least fixed point of $T_{\sigma}(p)$ applied to the abstract version of $append$, depicted in Figure 2 (right). In the first iteration of the evaluation we collect an abstract atom of the form $\pi_1 = append(\emptyset, \{Ys\}, \{Ys\})$ corresponding to fact (1’) in Figure 2, characterizing the set of atoms in which the first argument is ground and the second and third arguments are equal terms. In the second iteration a renaming of $\pi_1$ is unified with the body of clause (2’) in Figure 2. Abstract unification in this case specifies that $Xs$ is bound to $\emptyset$ (a ground term) and that $Ys$ and $Zs$ are bound to the same set (variable $Ys'$). Consequently the head of clause (2’) under such bindings can be represented as $\pi_2 = append(\{X\}, \{Ys'\}, \{X,Ys'\})$. This abstract atom describes the concrete atoms of the form $append(t_1, t_2, t_3)$ which exhibit sharing between $t_1$ and $t_3$ and between $t_2$ and $t_3$. Note that $\{\pi_2\} \approx \{\pi_1, \pi_2\}$ since $\pi_1 \preceq \pi_2$ with $\pi_1 = \pi_2 : \{X \mapsto \emptyset\}$. An additional iteration results in a new abstract atom of the form $\pi_3 = append(\{X, X'\}, \{Ys'\}, \{X, X', Ys'\})$, which is equivalent to $\pi_2$.

Thus, the fixed point is reached with $lfp(T_{\sigma}(p)) = \{ append(\{X\}, \{Y\}, \{X,Y\}) \}$ providing an approximation of sharing information for $append$.

7 Extensions to Set Logic Programs

Traditionally, sharing analyses have been enhanced with other kinds of information like linearity and freeness. This information is interesting in its own right, since it allows for further compile-time optimizations. Besides, it can significantly improve sharing information.

It is often said that properties such as linearity are hard to deal with in program analysis because they are not downwards-closed. Namely, $t$ may be a linear term but $\theta t$ non-linear. Note that our domain is downwards-closed with respect to the ordering “$\preceq$” (not with respect to the standard instantiation ordering). Consequently, downwards closure of the abstract domain preserves linearity. As a result, linearity can be captured straightforwardly by annotating variables in an adequate way, i.e., by distinguishing between linear and non-linear abstract terms. Unification is extended accordingly (see [5]). Freeness can also be added in a similar way.

Incorporating term structure to sets substitutions can also be done in a natural way. Abstract substitutions can be obtained by considering terms constructed very much like in the concrete case, but using (annotated) set expressions instead of variables. In order to guarantee finiteness of the domain, and termination of the analysis, the classical depth-$k$ bound on terms can be imposed. Similar extensions to sharing analysis with structural information have been proposed in
basis on the formalism of abstract equation systems, and in the $\text{Pat}(\mathcal{R})$ domain [6]. Arguably, we expect that the extension sketched here offers advantages of easy design and formal justification.

8 Conclusion

We have described an alternative and isomorphic representation of an abstract domain for sharing analysis. The new domain based on set logic programs leads to intuitive definitions for the abstract operations needed to provide for sharing analyses. This in itself is an advantage over the existing definitions which are hard to motivate and justify. The definitions given in this paper have been extended also for linearity information. It is straightforward to also extend them for term structure information. Top-down and bottom-up analyses based on these domains have been fully implemented. The current prototypes are not as efficient as carefully handcrafted interpreter-based analyzers for goal-dependent analysis, but are comparable for goal-independent analysis. Current efforts are being devoted to more efficient unification algorithms.
